

Verification Manual

Table of contents

Verified capabilities	1
Solid mechanics	1
How verification becomes documentation	1

This manual presents the engineering evidence used to assess Coreform IGA for Abaqus. Each study defines a problem, identifies its reference solution, and reports the numerical checks used to evaluate Coreform IGA.

The reported results are processed directly from automated verification runs. Figures, tables, and downloadable artifacts are generated from those results when the manual is built, reducing manual transcription and keeping the published evidence aligned with the tested software.

Verified capabilities

The verification hierarchy is organized by physical capability. The Coreform IGA discretization currently consists of trimmed three-dimensional solid elements; it does not provide one-dimensional beam or two-dimensional shell elements.

Solid mechanics

5 verification studies

Linear elastic stress

Verify stress fields, stress concentrations, load and boundary-condition types, multiple materials, and curved trimmed boundaries under small-strain linear elasticity.

How verification becomes documentation

Each study begins with a defined engineering problem and acceptance criteria. Automated tests run Coreform IGA, collect the relevant solution quantities, and compare them with an accepted analytic or numerical reference.

The manual is authored with [Quarto](#). During a documentation build, Quarto reads the completed test results, computes the summaries used in tables, generates plots with Matplotlib, requests visualizations from ParaView where appropriate, creates download links, and combines those outputs with the engineering explanation on each page.

Figure 1: High-level workflow from product development to published verification evidence.

This workflow makes the relationship between a verification claim and its supporting evidence visible to readers while allowing the explanatory prose to remain clear and focused on engineering interpretation.
